Abstract. Summarizing the evidence concerning medical interventions is an immense undertaking, in part because unstructured Portable Document Format (PDF) documents remain the main vehicle for disseminating the results of clinical trials. Clinicians and researchers must therefore manually extract and synthesise information from these PDFss to be published in *systematic reviews.* We introduce Spá,[4,5] a web-based viewer that enables automated annotation and summarisation of PDFs via machine learning (ML). To illustrate its functionalility, here we use Spá to semi-automate the assessment of bias in clinical trials. Spá can visualize the output from hybrid models that simultaneously classify documents (e.g., identifying trials as low or high risk of various biases), and annotate sentences that support these classifications. The Spá architecture is modular and new models may be trivially added, thus the tool made be widely useful in other domains with a PDF-based literature, including law, physics, and biology.

1 Introduction

Imposing structure on full-text documents (e.g., identifying specific sentences of interest) is an important and practical task in natural language processing and machine learning, because doing so manually is laborious and costly. *Systematic reviews* are an instructive example. Such reviews aim to answer clinical questions by exhaustively identifying and extracting information from all published relevant studies. They are fundamental tools in Evidence-based Medicine (EBM) [2]. The end product of a systematic review is an exhaustive synthesis (textual and statistical) of the current evidence. To produce these, reviewers must manually extract data on trial design and conduct, intervention effectiveness, adverse effects,

and potential biases from the free-text of published studies. These extraction tasks can be semi-automated using machine learning approaches. As an example, here we consider the task of bias assessment, in which a reviewers assess, e.g., whether study participants and personnel were properly blinded.

Assessing this is a time-consuming task: a single trial can take a domain expert around ten minutes [3]. Making matters worse, a single review may typically include several dozen trials, and due to low rates of reviewer agreement it is regarded as best practice to have each study assessed twice by independent reviewers who later come to a consensus [4]. Machine learning methods provide the machinery to automate such extractions; as they can effectively impose the desired structure onto PDFs. But if such technologies are to be practically useful, we need tools that visualize these model predictions and annotations. Here we describe Spá, which aspires to realize this aim.

Spá is an open-source, web-based tool that can incorporate state-of-the-art machine learning predictors to automatically annotate PDF articles. As a practical demonstration of this technology, we have built a machine learning system that automatically annotates PDFs to aid EBM. Specifically, this system leverages a multi-task model that simultaneously assesses the risk of biases across several domains. This tool is unique in that it leverages state-of-the-art machine learning (ML) models applied to full-text articles to assist practitioners of EBM.

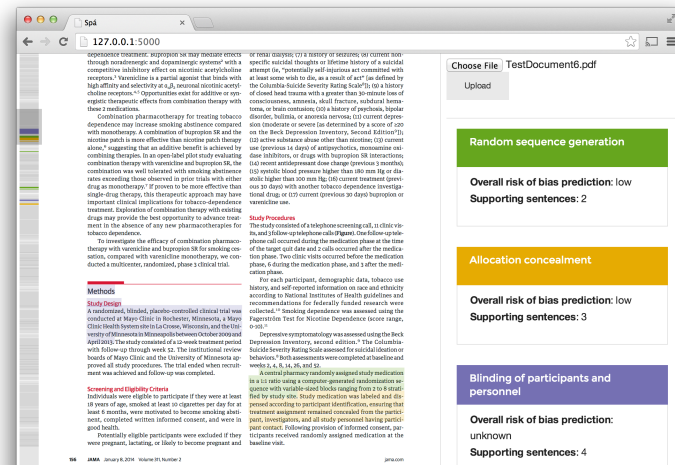

Fig. 1. Screenshot of a PDF with highlighted risk of bias. Here the risk of bias is assessed to be low, for example, and one of the supporting sentences for this assessment describes the randomization procedure (highlighted in green).

While our application of interest is EBM, we emphasize that the visualization tool can be used for any domain in which one wants to annotate PDFs. Thus the contribution of this work is two-fold, as we present: (1) a practical tool that incorporates machine learning to help researchers rapidly assess the risk of

biases in published biomedical articles, and, (2) a general open-source web tool for visualizing the predictions of trained models from full-text articles. These contributions are described further in Sections 2 and 3.

2 Automating Evidence-based Medicine

2.1 Machine Learning Approaches

We briefly describe our model for assessing the study risk of bias (and supporting sentences) across the following domains: random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, incomplete outcome data and selective reporting. To train our model, we have leveraged the Cochrane Database of Systematic Reviews (CDSR) in lieu of manually annotated data, which would be expensive to collect. The CDSR contains descriptions and data about clinical trials reported in existing systematic reviews. Briefly, we match (the full-texts of) studies to entries in the CDSR, which contains risk of bias assessments; this provides document level labels. The CDSR also contains sentences that annotators indicated as supporting their assessments. We match these strings to substrings in the PDFs to provide sentence-level supervision. This can thus be viewed as a *distantly supervised* [5,6] approach.

From a ML vantage, we have two tasks for a given article: (1) predict the overall risk of bias for each of the domains of interest, and (2) extract the sentences that support these assessments. For both tasks we leverage standard bag-of-words text encoding and linear-kernel Support Vector Machines (SVMs). Because the risk of bias predictions are correlated (across domains), we take a *multi-task* [7] approach to classification and jointly learn a model for the domains. We accomplish this by way of a feature space construction that includes both shared and domain-specific terms (similar to the domain adaptation approach in [8]). Furthermore, we take a unified approach to the two tasks by *jointly* assessing the risk of bias associated with a given article *and* extracting the sentences that support this judgment. Specifically, we first make sentence level predictions (using one set of trained models), and then insert features representing the tokens (words) in the predicted sentences for exploitation by the document level classifier (further details specified in [9]). Figure 1 shows example system output: in this case the overall risk of bias with respect to random sequence generation is judged to be low, and the supporting sentence for this judgement is highlighted in green.

3 Spá Architecture Overview

Spá relies on Mozilla pdf.js[6] for visualization of the document and text extraction. The results of the text extraction are processed server-side by a variety of processing topologies, as outlined in figure 2. Results, which could come from

---

[6] http://mozilla.github.io/pdf.js

complicated machine learning systems, are communicated back to the browser and displayed using React components.[7]

For each of the annotations the relevant nodes in the document are highlighted. A custom scrollbar[8] that acts as a 'mini-map' is projected to show where annotations reside within the document. The user can interactively activate and inspect specific results.

4   Future work

We have presented a web-based tool for visualization of annotations and summarizations for PDF documents. It allows users to see the results from machine learning predictions for a specific document. We have demonstrated the use of this system within the context of EBM by automatically extracting potential risks of bias (and supporting sentences) via state-of-the-art ML methods.

More generally, we believe the tool to be potentially useful for a much wider range of text mining and machine learning applications. To increase the generality of the tool we are developing a pluggable system for processing topologies, allowing developers to quickly plug in new ML systems for automated PDF annotation. Furthermore, we are working to allow users to save selected annotations, possibly embedded within the document itself, for sharing and off-line use. The vision is to have an extensible system for semi-automated (machine assisted) screening, data extraction and data summarization for EBM, and to allow rapid development of similar systems for other domains.
